中山大学软件学院 2011 级软件工程专业(2012学年秋季学期)

《数值分析》期中试题(B卷)

(考试形式: 闭 卷 考试时间: 2 小时)

方向:	姓名:	学号:
79 31	/ 	· · ·

- 1. Fill in the blanket with proper answers (5 marks each, total 30 marks)
 - 1) Suppose x = 0.544987104184, then the approximate value 0.544986720817 has __6__ significant digits.

2) Let
$$A = \begin{pmatrix} 0 & 1 & 1 & 4 \\ 5 & 2 & -1 & 0 \\ 1 & 5 & 2 & 2 \\ 2 & -3 & 0 & 6 \end{pmatrix}$$
, then $||A||_1 = \underline{12}$, $||A||_{\infty} = \underline{11}$.

3) The recursive rule of secant method for solving nonlinear equation f(x)=0 is

$$p_{k+1} = p_k - \frac{f(p_k)}{f(p_k) - f(p_{k-1})} (p_k - p_{k-1})$$

and its speed of convergence is $\frac{1+\sqrt{5}}{2}$.

- 4) The function $g(x) = -4 + 4x \frac{1}{2}x^2$ has ______ fixed points, and the fixed point x=4 is attractive.
- The process of Gaussian elimination with back substitution for solving the linear systems Ax = b, where A is an $n \times n$ matrix, requires $\frac{n^3}{3} + \frac{n^2}{2} - \frac{5n}{6}$

multiplications and
$$\frac{n(n+1)}{2}$$
 divisions.

说明: 消去的过程乘法的次数为 $\frac{n^3-n}{3}$, 除法的次数为 $\frac{n(n-1)}{2}$ 。回带是解上三

角方程组,乘法的次数为 $0+1+2+...+(n-1)=\frac{n(n-1)}{2}$, 除法的次数为 \underline{n} 。

6) For the linear system,

$$\begin{cases} 2x - y = -4 \\ x + 3y = -2 \end{cases}$$

starting with $(x_0, y_0) = (1, 2)$, the Gauss-Seidel iteration process yields

$$\left(\mathbf{x}_{1},\mathbf{y}_{1}\right) = \left(-1,-\frac{1}{3}\right).$$

the Jacobi iteration process yields $(x_1, y_1) = \underline{(-1, -1)}$.

2. (20 marks)Consider the division of two numbers x, y with the approximate value x^* , y^* , analyzing the propagation of relative error.

解: 记
$$\varepsilon_x = x^* - x$$
, $\varepsilon_y = y^* - y$ 则
$$\frac{x^*}{y^*} - \frac{x}{y} = \frac{x + \varepsilon_x}{y + \varepsilon_y} - \frac{x}{y} = \frac{y\varepsilon_x - x\varepsilon_y}{y(y + \varepsilon_y)}$$

$$= \frac{\varepsilon_x}{(y + \varepsilon_q)} - \frac{x\varepsilon_y}{y(y + \varepsilon_y)}$$

$$\approx \frac{1}{y} \varepsilon_x - \frac{x}{y^2} \varepsilon_y$$

所以

$$\frac{\frac{x^*}{y^*} - \frac{x}{y}}{\frac{x}{y}} \approx \frac{1}{y} \left(\varepsilon_x - \frac{x}{y} \varepsilon_y \right) = \frac{1}{x} \left(\varepsilon_x - \frac{x}{y} \varepsilon_y \right) = \frac{\varepsilon_x}{x} - \frac{\varepsilon_y}{y}$$

即除法的相对误差等于分子的相对误差与分母的相对误差之差!

 $=\frac{1}{v}\left(\varepsilon_x-\frac{x}{v}\varepsilon_y\right)$

3. (20 marks)Write down the cubic Lagrange interpolation to the function

$$f(x) = x^4 - 2x^3$$

where interpolation is to be exact at the four nodes $x_0 = -1, x_1 = 0, x_2 = 1, x_3 = 3$.

解:

X	-1	0	1	3
f(x)	3	0	-1	27

于是

$$L(x) = 3 \cdot \frac{x(x-1)(x-3)}{(-1)\cdot(-2)\cdot(-4)} - \frac{x(x+1)(x-3)}{1\cdot 2\cdot(-2)} + 27 \cdot \frac{x(x+1)(x-1)}{4\cdot 3\cdot 2}$$
$$= x^3 + x^2 - 3x$$

4. (10 marks)How to select the initial value x_0 , so that the fixed point iteration $\{x_n\}$ defined

by
$$x_n = \varphi(x_{n-1})$$
, where $\varphi(x) = \frac{2 - e^x}{5}$, always converges?

解:可以根据压缩映射定理来选择初值。容易证明 $\varphi(x)$ 是闭区间 $\left[-1,1\right]$ 上的压缩映射。

事实上,
$$\varphi(x)$$
 单调下降,于是当 $x \in [-1,1]$ 时

$$-1 \le \varphi(1) \le \varphi(x) \le \varphi(-1) \le 1$$

$$\left| \varphi'(x) \right| = \left| -\frac{e^x}{5} \right| \le \frac{e}{5} < 1$$

于是初值 x_0 可以选[-1,1]中的任意一点。

5. (20 marks) Find the triangular factorization PA = LU for the following matrix

$$A = \begin{bmatrix} 0 & 2 & 3 \\ 1 & 2 & 6 \\ 2 & 2 & 4 \end{bmatrix}$$

解:

$$\begin{bmatrix} 0 & 2 & 3 \\ 1 & 2 & 6 \\ 2 & 2 & 4 \end{bmatrix} \rightarrow \begin{bmatrix} 0 & 2 & 3 \\ 1 & 2 & 6 \\ 2 & 2 & 4 \end{bmatrix} \rightarrow \begin{bmatrix} 0 & 2 & 3 \\ \frac{1}{2} & 1 & 4 \\ 2 & 2 & 4 \end{bmatrix}$$

$$p = (1,2,3) \quad p = (3,2,1)$$

$$p = (3,2,1)$$

$$p = (3,2,1)$$

$$p = (3,2,1)$$

$$p = (3,1,2)$$

$$p = (3,1,2)$$

所以

$$P = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, L = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ \frac{1}{2} & \frac{1}{2} & 1 \end{pmatrix}, U = \begin{pmatrix} 2 & 2 & 4 \\ 0 & 2 & 3 \\ 0 & 0 & \frac{5}{2} \end{pmatrix}$$
